9 **ABSTRACT**

10 Due to their distinctive features, multiteam systems (MTSs) face significant coordination  
11 challenges—both within component teams and across the larger system. Despite the benefits of  
12 informal mechanisms of coordination for knowledge-based work, there is considerable  
13 ambiguity regarding their effects in MTSs. To resolve this ambiguity, we build and test theory  
14 about how interpersonal interactions among MTS members serve as an informal coordination  
15 mechanism that facilitates team and system functioning. Integrating MTS research with insights  
16 from the team boundary spanning literature, we argue that the degree to which MTS members  
17 balance their interactions with members of their own component team (i.e., intrateam  
18 interactions) and with the members of other teams in the system (i.e., inter-team interactions)  
19 shapes team- and system-level performance. The findings of a multimethod study of 44 MTSs  
20 composed of 295 teams and 930 people show that as inter-team interactions exceed intrateam  
21 interactions, team conflict rises and detracts from component team performance. At the system  
22 level, balance between intra- and inter-team interactions enhances system success. Our findings  
23 advance understanding of MTSs by highlighting how informal coordination mechanisms enable  
24 MTSs to overcome their coordination challenges and address the unique performance tension  
25 between component teams and the larger system.

29

30  
31 As the industrial landscape shifted to an increasingly knowledge-driven economy, early  
32 commentators (e.g., Drucker, 1999) directed attention to the unique challenges faced by  
33 individual knowledge workers. Subsequent scholarship (e.g., Wuchty, Jones, & Uzzi, 2007)  
34 redirected attention to teams as the locus of knowledge work, arguing that individual workers  
35 alone lack the capacity needed to solve problems of increasing scope and complexity. Most  
36 recently, scholars (e.g., Edmondson & Harvey, 2018; Zaccaro, Dubrow, Torres, & Campbell,  
37 2020) have highlighted the rising prominence of knowledge work in multiteam systems  
38 (MTSs)—“two or more teams that interface directly and interdependently in response to  
39 environmental contingencies toward the accomplishment of collective goals” (Mathieu, Marks,  
40 & Zaccaro, 2001: 290). Similar to the shift from the individual to the team, the shift from the  
41 team to the MTS has occurred because the complexity of many modern problems exceeds the

3 capabilities of any single team (Zaccaro et al., 2020).  
4

5           As MTSs seek to address complex knowledge-based problems, theory and research have  
6 revealed that coordination—“the process of interaction that integrates a collective set of  
7 interdependent tasks” (Okhuysen & Bechky, 2009: 463)—is particularly important, but also  
8 especially difficult, for MTS functioning (e.g., Davison, Hollenbeck, Barnes, Slesman, & Ilgen,  
9 2012; de Vries, Hollenbeck, Davison, Walter, & van der Vegt, 2016; Rico, Hinsz, Davison, &  
10 Salas, 2018; Shuffler & Carter, 2018). Distributing tasks across teams offers the promise of  
11 specialized expertise or focused effort to solve distinct elements of a larger and more complex  
12 problem; but, the overall benefit to the system can only be realized if members effectively  
13 coordinate both within and across team boundaries. Doing so is especially difficult for MTSs  
14 because structural and psychological barriers—emerging from a division of labor, specialization  
15 of expertise, and unique priorities—stymie the flow of information between teams (Heath &  
16 Staudenmayer, 2000). As a function of these barriers, scholars have highlighted inter-team  
17 coordination, in particular, as a primary contributor to the success or failure of MTSs (e.g.,  
18 DeChurch & Marks, 2006; Firth, Hollenbeck, Miles, Ilgen, & Barnes, 2015). Understanding how  
19 to facilitate inter-team coordination, without degrading intrateam coordination, has been a central  
20 focus of MTS research (Rico et al., 2018; Zaccaro et al., 2020).

41           Theory (e.g., Katz & Kahn, 1978; Thompson, 1967) and research (e.g., Faraj & Sproull,  
42 2000; Van de Ven, Delbecq, & Koenig, 1976) highlight that informal coordination  
43 mechanisms—entailing direct, mutual, and ad hoc interactions between people (Okhuysen &  
44 Bechky, 2009)—are useful for accomplishing collective knowledge-based work. Given that  
45 MTSs are frequently deployed to address such problems (Zaccaro et al., 2020), past theory and  
46 research on coordination would seemingly suggest that informal mechanisms should be

1  
2  
3 especially helpful for enabling MTS effectiveness. Yet, the degree to which informal  
4 mechanisms are beneficial or detrimental for MTS effectiveness remains unclear, in part,  
5 because prior studies have largely focused on formal structural (e.g., de Vries et al., 2016), role-  
6 based (e.g., Davison et al., 2012), and centralized (e.g., Lanaj, Hollenbeck, Ilgen, Barnes, &  
7 Harmon, 2013) mechanisms of coordination (Mathieu, Luciano, & DeChurch, 2018). Moreover,  
8 the findings of the few quantitative studies that have measured informal coordination are  
9 ambiguous, leading to contradictory recommendations about whether or how MTS members  
10 should use informal mechanisms to facilitate coordination (e.g., Davison et al., 2012; Marks,  
11 DeChurch, Mathieu, Panzer, & Alonso, 2005; Mell, DeChurch, Contractor, & Leenders, 2020).  
12 Thus, while broader coordination theory and research generally prescribe the use of informal  
13 mechanisms for knowledge-based work, there is considerable inconsistency regarding the  
14 usefulness of these mechanisms for enabling coordination in MTSs.

30  
31 The purpose of this paper is to build and test theory that resolves this ambiguity about  
32 how informal coordination mechanisms—specifically, direct interpersonal interactions among  
33 MTS members—influence the effectiveness of MTSs engaged in knowledge-based work. While  
34 prior MTS research on informal mechanisms has assessed their intrateam and inter-team effects  
35 independently, MTSs face the unique challenge of simultaneously coordinating activities within  
36 and between component teams. To address this challenge and the associated ambiguity, we  
37 develop new insights into informal coordination in MTSs by integrating MTS scholarship with  
38 broader theory and research on activities commonly known as boundary spanning—a “team’s  
39 actions to establish linkages and manage interactions with parties in the external environment”  
40 (Marrone, 2010: 914). The MTS and boundary spanning literatures share a focus on how team  
41 members engage with those outside of team boundaries, which for MTS members involves inter-

2  
3 team interactions. However, because they are interested in outcomes at different levels of  
4 analysis, with MTS researchers focused principally on the system level and boundary spanning  
5 researchers on the team-level, the theoretical bases of these literatures emphasize different  
6 constellations of processes. We integrate these two perspectives to derive the insight that the  
7 degree of balance of MTS members' intrateam and inter-team interactions shapes team  
8 processes—specifically, team conflict—and team- and system-level performance.  
9

10  
11 We test our theoretical model in a study of 44 multiteam systems, composed of 295 teams  
12 and 930 people, charged with completing a knowledge-based engineering task over eleven  
13 weeks. Our findings make three main contributions to the MTS literature. First, our focus on  
14 informal coordination extends past studies in the MTS literature, which have yielded ambiguous  
15 conclusions regarding informal mechanisms (Carter, Cullen-Lester, Jones, Gerbasi, Chrobot-  
16 Mason, & Nae, 2020; Luciano, DeChurch, & Mathieu, 2018; Rico et al., 2018; Zaccaro et al.,  
17 2020). Given the documented importance of within- and between-team coordination for MTS  
18 effectiveness (Zaccaro et al., 2020), paired with the documented value of informal mechanisms  
19 for other forms of complex knowledge-based work (e.g., Faraj & Sproull, 2000), resolving  
20 ambiguity regarding the role of informal coordination mechanisms advances MTS theory and  
21 offers guidance for practice. Our findings challenge the oft-stated view that MTSs are too large,  
22 complex, and distributed to benefit from informal coordination (e.g., Davison et al., 2012; Lanaj  
23 et al., 2013), calling attention to informal interactions as a facilitator of MTS effectiveness.  
24

25  
26 Second, by examining the balance of intrateam and inter-team interactions, our research  
27 takes into account the unique performance tensions in MTSs to help resolve ambiguity in the  
28 findings of the few studies that have considered informal coordination in MTSs (e.g., Davison et  
29 al., 2012; Marks et al., 2005; Mell et al., 2020). Deriving new insights by integrating the MTS

2  
3 and boundary spanning literatures, our coincident consideration of intrateam and inter-team  
4 interactions enriches prior MTS research, which has often treated within-team and between-team  
5 dynamics as separate, additive contributors to coordination. We also identify team conflict as a  
6 mechanism that channels the effects of an imbalance of intrateam and inter-team interaction  
7 patterns to team effectiveness. Even as inter-team interactions are necessary for system-level  
8 coordination, when not balanced by corresponding intrateam interactions, conflict emerges and  
9 hinders team performance. Our joint consideration of intrateam and inter-team interactions—  
10 specifically, their balance at the team and system levels—thus advances understanding of the  
11 potential “countervailing or confluent consequences of coordination processes” in MTSs (Rico et  
12 al., 2018: 11), offering implications for how to overcome the performance tensions that are  
13 inherent to MTSs (Luciano et al., 2018; Mathieu et al., 2018).

25  
26  
27

28 Although not the main contribution of the paper, but complementing our theoretical  
29 contributions, attributes of our study help address limitations in the MTS literature that scholars  
30 have recently spotlighted (e.g., Shuffler & Carter, 2018; Zaccaro et al., 2020). Our study of  
31 MTSs completing a generative engineering task enriches the diversity of MTS research in terms  
32 of task type (i.e., structured vs. unstructured), interaction medium (i.e., computer mediated vs.  
33 face-to-face), and size (i.e., relatively small versus large number of component teams).  
34

40  
41

42 Additionally, we use wearable sensors to measure interpersonal interactions among MTS  
43 members—an approach that scholars have advocated for assessing coordination in MTSs in a  
44 fine-grained way (e.g., Luciano et al., 2018; Mathieu et al., 2018; Shuffler & Carter, 2018;  
45 Zaccaro et al., 2020). Wearable sensors enabled us not only to test our a priori hypotheses, but  
46 also to examine post-hoc how different foci and forms of interactions relate to MTS  
47 effectiveness. Together, these hypothesized and post hoc examinations suggest new directions

3 for future research on coordination in MTSs.  
4

### 5 THEORETICAL DEVELOPMENT

6  
7 Coordination challenges are particularly acute within MTSs due to two of their distinctive  
8 characteristics. First, an MTS's goals are hierarchical, with at least two levels. At the proximal  
9 level, each component team has its own specific goals; at the distal level, the system has a  
10 superordinate goal that requires input from the component teams (Mathieu et al., 2001). This  
11 goal hierarchy creates structural interdependencies among component teams (Zaccaro et al.,  
12 2020) and contributes to potential performance tensions between the local component teams and  
13 the global system as a whole (Shuffler & Carter, 2018). Second, MTS component teams are  
14 structurally differentiated, with particular goals, norms, and processes that reinforce distinctions  
15 between teams (Luciano et al., 2018). Together, these attributes can be barriers to simultaneously  
16 achieving coordination in the two areas where it is necessary (DeChurch & Marks, 2006).  
17  
18 Intrateam coordination—the integration of activities among the members of the same component  
19 team—is needed for teams to realize their local, proximal goals. Inter-team coordination—the  
20 integration of activities across teams within the system—is needed to achieve the global, distal  
21 objectives of the MTS as a whole.

33  
34  
35  
36  
37  
38

39 In trying to understand how organizations integrate their activities, researchers have  
40 studied a wide range of coordination mechanisms (Okhuysen & Bechky, 2009)—ways that  
41 people integrate their activities when engaged in interdependent work. Scholars often make a  
42 basic distinction between coordination mechanisms that are formal and those that are informal  
43 (e.g., Faraj & Xiao, 2006; Van de Ven et al., 1976). Formal mechanisms are impersonal and top-  
44 down—leaders deploy them with little concern for the idiosyncratic attributes and characteristics  
45 of individual members (Van de Ven et al., 1976). Informal mechanisms, in contrast, are personal  
46 and emerge organically; they entail direct, mutual, and real-time adjustments between people to  
47  
48  
49  
50  
51

1  
2  
3 facilitate the integration of their work (Van de Ven et al., 1976). The most ubiquitous informal  
4 mechanism in organizations—and the focus of our research—are interpersonal interactions: the  
5 direct, bi-directional exchange of information between two people (Katz & Kahn, 1978). Time  
6 spent in interpersonal interactions enables individuals to mutually adjust their activities and  
7 better integrate their work. To capture this fundamental informal coordination mechanism, we  
8 focus our research specifically on the duration of MTS members' interactions with one another.  
9  
10 As MTSs must realize coordination both within and between teams (Luciano et al., 2018), we  
11 consider two kinds of interactions: intrateam and inter-team interactions. Intrateam interactions  
12 are encounters among the members of the same component team; inter-team interactions are  
13 encounters among the members of different component teams within the same MTS.  
14  
15  
16  
17  
18  
19  
20  
21  
22  
23  
24  
25

26 Due to the size and complexity of MTSs, scholars have extolled the benefits of formal  
27 coordination mechanisms (DeChurch & Marks, 2006; Lanaj et al., 2013). And, indeed, a review  
28 of the MTS literature reveals that the vast majority of published studies—particularly those using  
29 quantitative methods—have documented the value of various formal mechanisms for enabling  
30 system-level effectiveness. For example, MTS researchers have found that coordination can be  
31 enhanced through the use of a well-defined, hierarchical structure that features a higher-order  
32 “integration team” (Davison et al., 2012; de Vries et al., 2016). Researchers have also found  
33 performance benefits from centralized a priori planning (Lanaj et al., 2013) and pre-task formal  
34 frame of reference training (Firth et al., 2015). Overall, existing research clearly demonstrates  
35 the value of formal mechanisms for MTS coordination and system effectiveness.  
36  
37  
38  
39  
40  
41  
42  
43  
44  
45  
46  
47  
48

49 The picture is far less clear regarding the effects of informal coordination mechanisms on  
50 MTS functioning. On the one hand, with few exceptions—like Mell et al.'s (2020) study of  
51 information sharing—research has rarely directly studied the interpersonal interactions that are  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 an informal means of coordinating activities. Rather than assessing interpersonal interactions,  
4  
5 past studies that have forwarded conclusions about informal coordination have drawn inferences  
6  
7 from, for example, synchronous activity (e.g., Davison et al., 2012) or from the effects of a  
8  
9 multifaceted set of action processes (e.g., Marks et al., 2005). On the other hand, papers that  
10  
11 have alluded to informal mechanisms in MTSs—particularly with respect to inter-team  
12  
13 coordination—have presented ambiguous empirical findings (e.g., Davison et al., 2012; Mell et  
14  
15 al., 2020), and the resulting interpretations have suggested rather broad pessimism (Rico, Hinsz,  
16  
17 Burke, & Salas, 2017). Davison et al. (2012: 809), for example, argued that “direct mutual  
18  
19 adjustment among all members in the collective...is actually detrimental to performance in  
20  
21 multiteam systems”—a view echoed by Lanaj et al. (2013: 737), who asserted that “multiteam  
22  
23 systems are too large to support mutual adjustment among all team members.”  
24  
25  
26  
27

28  
29 The dearth of research on informal mechanisms in the MTS literature, and the relatively  
30  
31 pessimistic view of their system-level effects, is perplexing, given broader theory and research  
32  
33 on coordination in knowledge-based work (e.g., Faraj & Xiao, 2006; Heath & Staudenmayer,  
34  
35 2000; Van de Ven et al., 1976). Outside the MTS literature, informal mechanisms are viewed as  
36  
37 essential for enabling coordination for information-intensive collective tasks—tasks for which  
38  
39 “...coordination is less dependent on structural arrangements and more contingent on knowledge  
40  
41 integration” (Faraj & Xiao, 2006: 1155). This body of broader theory and research suggests that  
42  
43 informal mechanisms should be especially valuable for work that is complex, uncertain, and  
44  
45 interdependent (Choi, 2002)—like the knowledge-based problems that MTSs often address.  
46  
47  
48

49  
50 To begin to resolve equivocality regarding informal coordination in MTSs, we propose a  
51  
52 conceptual model—depicted as Figure 1—that delineates how interpersonal interactions among  
53  
54 members influence MTS processes and outcomes. Integrating prior findings from the MTS  
55  
56  
57  
58  
59  
60

1  
2  
3 literature with insights from the team boundary spanning literature (e.g., Choi, 2002), our core  
4 assertion is that how individuals balance their interpersonal interactions—between the members  
5 of their own component team and the members of other teams in the system—shapes whether  
6 informal interactions help or hinder the effectiveness of the team and system.

### 16 **Informal Coordination Mechanisms and Component Team Effectiveness**

17  
18 For an MTS to achieve its global system-level objectives, the component teams within it  
19 must first achieve their local team-level objectives. How informal mechanisms influence the  
20 internal functioning of component teams—a topic studied extensively in broader research on  
21 teams—has been of lesser concern in the MTS literature. Instead, and reflecting the unique  
22 characteristics of MTSs, scholars have foremost sought to understand how to enable the  
23 between-team coordination needed to achieve system-level outcomes (Carter et al., 2020;  
24 Zaccaro et al., 2020). To formulate predictions about how informal interactions shape component  
25 team processes and outcomes in MTSs, we derive insights from theory and research on team  
26 boundary spanning (Ancona, 1990; Marrone, 2010). From a boundary spanning perspective,  
27 inter-team interactions in an MTSs are one—but certainly not the only—form of boundary  
28 spanning behavior (Marrone, 2010). Although centered on traditional, standalone teams, the  
29 boundary spanning literature provides complementary insights that aid in developing predictions  
30 about how interpersonal interactions influence component teams in MTSs. Whereas the focus of  
31 MTS research on inter-team interactions has been system-level outcomes, the focus of boundary  
32 spanning research on inter-team interactions has been team-level effectiveness (Marrone, 2010).  
33

47  
48  
49  
50  
51  
52

53 The team boundary spanning literature forwards a nuanced view of the effects of inter-  
54 team interpersonal interactions (Choi, 2002; Marrone, 2010). When team members venture  
55  
56  
57  
58  
59  
60

1  
2  
3 beyond the boundaries of their own team, they are able to secure resources, gain support and—  
4  
5 importantly for the context of MTSs—align their activities with other organizational units  
6  
7 (Ancona, 1990; Ancona & Caldwell, 1992; Marrone, Tesluk, & Carson, 2007). However, it takes  
8  
9 time and effort to seek out, engage with, and procure resources from external teams; and, it  
10  
11 requires internal coordination to implement or use those resources (Marrone et al., 2007). For  
12  
13 these reasons, when not balanced with corresponding internal coordination efforts, extensive  
14  
15 boundary spanning behavior can breed divergence in team members' conceptualizations of their  
16  
17 tasks and spark disagreements about how to best accomplish their team's objectives (Choi, 2002;  
18  
19 Faraj & Yan, 2009; Marrone, 2010). These symptoms are indicative of intrateam conflict—  
20  
21 unpleasant disagreements among team members regarding their work (Jehn & Bendersky,  
22  
23 2003)—which may serve as an important intermediary mechanism for understanding how  
24  
25 informal mechanisms relate to component team effectiveness in MTSs (Lanaj, Foulk, &  
26  
27 Hollenbeck, 2018). Although conflict can be sparked by a range of issues—elements of a task,  
28  
29 aspects of work processes, or relationships among members (Jehn, Northcraft, & Neal, 1999)—it  
30  
31 is often experienced in a diffuse way, with one form spilling over to others (de Wit, Greer, &  
32  
33 Jehn, 2012). For this reason, although task-based disagreements can sometimes facilitate  
34  
35 knowledge-based work, conflict often undermines team effectiveness because it disrupts  
36  
37 collective information processing (De Dreu & Weingart, 2003), which is needed for MTS  
38  
39 members to integrate knowledge gained through their inter-team interactions.  
40  
41  
42  
43  
44  
45

46  
47 To redress potential disruption, boundary spanning theorists advocate that team members  
48  
49 balance external and internal activities (Choi, 2002; Marrone, 2010). As they increase their  
50  
51 boundary spanning, team members should engage in a corresponding amount of internal  
52  
53 interactions because effective boundary spanning "...requires the transmission of resulting  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 external information and knowledge back into the team itself” (Marrone, 2010: 930). When team  
4  
5 members engage with one another, internally, they can share new information acquired  
6  
7 externally and resolve potentially discrepant understandings of their task (Choi, 2002; Faraj &  
8  
9 Yan, 2009; Keller, 2001). In this regard, a balanced configuration creates synergies between  
10  
11 intra- and inter-team informal coordination efforts (Choi, 2002). The idea that external and  
12  
13 internal activities work in concert to influence team effectiveness has received support in  
14  
15 boundary spanning research on team coordination (Faraj & Yan, 2009), learning (Bresman,  
16  
17 2010; Cummings & Haas, 2012; Wong, 2004), and communication (Keller, 2001).  
18  
19  
20  
21

22 This core idea from the team boundary spanning literature—that balance between  
23  
24 external and internal activities is needed to leverage knowledge from outside the team and avoid  
25  
26 disruptive conflict—serves as a grounding principle for our hypotheses about how intrateam and  
27  
28 inter-team interactions influence component team processes and outcomes in MTSs. Within the  
29  
30 unique context of MTSs, external activities are not just beneficial, but essential (DeChurch &  
31  
32 Marks, 2006). The necessity of inter-team interactions does not, however, obviate their potential  
33  
34 costs in terms of intrateam conflict if not appropriately balanced with intrateam interactions.  
35  
36 Following boundary spanning theory, an excessive external focus, relative to internal  
37  
38 interactions, can increase role overload and undermine team viability—states that may breed  
39  
40 conflict among team members (Bresman, 2010; Bron, Endedijk, van Veelen, & Veldkamp, 2018;  
41  
42 Marrone et al., 2007; Wong, 2004). From a boundary spanning perspective, this type of  
43  
44 incongruence reflects an “underbounded” configuration—many external interactions without the  
45  
46 capacity to sufficiently coordinate team members to use the requisite knowledge and skills and  
47  
48 achieve their own local goals (Ancona & Caldwell, 1992). Thus, although theory suggests that  
49  
50 informal mechanisms are valuable for coordination in knowledge work, the key insight from the  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 boundary spanning literature is that a team must strike "...a balance between internal and  
4 external activities" (Choi, 2002: 187). When inter-team interactions exceed intrateam  
5 interactions, MTS component teams are likely to become embroiled in conflict.  
6  
7

8  
9  
10 *Hypothesis 1: Imbalance between intrateam and inter-team interactions is*  
11 *positively related to team conflict, such that team conflict is higher as inter-team*  
12 *interactions exceed intrateam interactions.*  
13

14  
15 Extending this hypothesis, we propose that an imbalance in intrateam and inter-team  
16 interactions has implications, indirectly through team conflict, for component team performance.  
17 There is robust evidence that conflict—especially disagreements about how to allocate resources  
18 and disputes that are emotionally charged—is detrimental for team performance. Meta-analyses  
19 have documented that, although disagreements about ideas may be helpful under some  
20 circumstances, team conflict generally is negatively related to team performance (De Dreu &  
21 Weingart, 2003; de Wit et al., 2012). Moreover, even helpful disagreements often spill over into  
22 destructive forms of conflict (e.g., Simons & Peterson, 2000).  
23  
24  
25  
26  
27  
28  
29  
30  
31  
32

33 For MTS component teams—entities that already face the challenge of allocating scarce  
34 resources—time spent resolving discrepant understandings of who is responsible for what or how  
35 the team will complete its work is time taken away from advancing toward their local objectives.  
36 Related research on boundary spanning similarly implicates team conflict as a mechanism that  
37 transmits the effects of an imbalance between external and internal activities to team  
38 performance (Choi, 2002). Bresman (2010: 82), for instance, suggested that an imbalance leads  
39 team members to view external activities as a "waste of time," reflecting conflict over the  
40 allocation of resources. Wong (2004: 647) argued that an imbalance will "increase cognitive  
41 variation in members' beliefs about their task and how things are done," implicitly implicating  
42 conflict as an important mechanism (Hinsz & Betts, 2011). Bron et al. (2018: 454) further noted  
43

2  
3 that teams that have a high external focus and low internal focus will struggle “to come to  
4  
5 within-team consensus and reach decisions”—a situation emblematic of team conflict.  
6

7  
8 *Hypothesis 2: Imbalance between intrateam and inter-team interactions is*  
9 *indirectly negatively related to team performance through team conflict.*  
10

### 11 **Informal Coordination Mechanisms and System-Level Effectiveness**

12  
13 Although component team effectiveness is a necessary building block for MTS  
14  
15 effectiveness, team effectiveness alone is insufficient (Marks et al., 2005). The teams within an  
16  
17 MTS must also coordinate their activities to realize effective system-level performance (Luciano  
18  
19 et al., 2018). MTS scholars have noted that performance-enabling mechanisms at one level—  
20  
21 such as effective within-team coordination—may have performance-inhibiting effects at the  
22  
23 other level (DeChurch & Zaccaro, 2010; Shuffler, Jiménez-Rodríguez, & Kramer, 2015). Given  
24  
25 these countervailing effects, “MTSs must be aware of team and MTS functioning at the same  
26  
27 time to balance needs” (Shuffler & Carter, 2018: 393).  
28  
29  
30

31  
32 Boundary spanning, across the system, can help achieve this simultaneous awareness of  
33  
34 the team and system. Extending the notion of boundary spanning to higher forms, Marrone  
35  
36 (2010) discussed network boundary spanning across mutually interdependent teams, such as  
37  
38 those that compose an MTS. Intraorganizational boundary spanning (e.g., Rosenkopf & Nerkar,  
39  
40 2001; Zhao & Anand, 2013) is a means for the exchange and integration of knowledge within a  
41  
42 broader system. Decentralized interactions between units in an organization can serve as a  
43  
44 “collective bridge” that enables knowledge transfer (Zhao & Anand, 2013). Organizational units  
45  
46 must balance their focus, spanning their boundaries to obtain external knowledge and engaging  
47  
48 in internal activities to integrate it. As Choi (2002: 189) asserted, “internal and external activities  
49  
50 may maintain synergistic relationships through mutual reinforcement.”  
51  
52  
53

54  
55 Balancing external and internal processes to coordinate information is thus likely  
56  
57  
58  
59  
60

1  
2  
3 paramount for MTS functioning. Interpersonal interactions may be important for coordinating  
4 laterally within and between teams, but may have opposing effects unless sufficient attention is  
5 placed on each (Rico et al., 2018). Disproportionately engaging in intrateam interactions may  
6 enable component teams to perform at a high level independently, but could contribute to a  
7 breakdown in between-team coordination. On the other hand, favoring inter-team interactions  
8 over intrateam interactions may impede system-level coordination because component teams will  
9 struggle to integrate necessary changes into their internal work (Rico et al., 2017). MTSs must  
10 have inter-team interactions to adjust at linkage points (Mell et al., 2020) and corresponding  
11 intrateam interactions to integrate these adjustments locally (Choi, 2002; Marrone, 2010).  
12  
13  
14  
15  
16  
17  
18  
19  
20  
21  
22  
23

24 Members of an MTS may be particularly at risk of becoming imbalanced in their  
25 intrateam and inter-team interactions. A primary reason that MTSs fail to achieve their system-  
26 level objectives is insufficient coordination between teams (Mathieu et al., 2018; Rico et al.,  
27 2017). That is, an imbalance—in either direction—is likely problematic for an MTS (Mathieu et  
28 al., 2018). Providing some peripheral support for these ideas, Firth et al. (2015) found in a study  
29 of a formal training program that the effectiveness of between-team coordination in an MTS  
30 depends on how well component teams coordinated their internal activities. Similarly, MTS  
31 researchers studying identification have found that an overemphasis on either the component  
32 team or the system can undermine system-level performance (Porck, Matta, Hollenbeck, Oh,  
33 Lanaj, & Lee, 2019). These findings lend credence to the idea that balance between intrateam  
34 and inter-team interpersonal interactions serves as an informal coordination mechanism that can  
35 enable system-level success in an MTS.

## METHOD

### Research Setting

We tested our hypotheses in a multi-source and multi-method study of MTSs that were formed as part of the laboratory component of a required undergraduate engineering course at a university on the East Coast of the United States. Students worked together in an MTS to design and build a Rube Goldberg machine—a complex, over-engineered device that completes a trivial or mundane task. The building block of a Rube Goldberg machine is the transfer of energy across events. For example, a marble rolls into and knocks over a sequence of dominos, triggering the release of a helium balloon to lift a switch that turns on a light. Within each laboratory section, students were first organized into component teams and each team was charged with the goal of constructing a Rube Goldberg machine comprising at least six prescribed energy transfer events. Each component team's Rube Goldberg machine was itself one part of a larger Rube Goldberg machine assembled by connecting all machines designed by the teams within that section. Teams were assigned an order and had to link their team's machine with adjacent teams' machines to create a larger, system-level Rube Goldberg machine. Thus, within each section, the teams needed to work together interdependently as an MTS to ensure the smooth transfer of energy between machines and through the system to complete the final goal. Throughout the 11-week course, each team had a separate physical workstation in the same classroom where, for roughly two hours per week, members worked on their component Rube Goldberg machine. Members were not restricted to only their workstation, though; they could move freely throughout the classroom to visit other teams' workstations to discuss and coordinate transfers of energy between machines within the larger system.

This task exemplifies the challenges faced by MTSs engaged in knowledge work, particularly in terms of structural differentiation and hierarchical goals. As the sample machine

1  
2  
3 layout depicted in Figure 2A shows, students formed a sequentially interdependent MTS (Rico et  
4 al., 2018), with reciprocal interactions between adjacent teams. Moreover, these teams had to  
5 complete a knowledge-based task involving complex (multiple and varied energy transfer  
6 events), specialized (each team develop their own unique machine), and interdependent (linkage  
7 between adjacent teams) requirements (Zaccaro et al., 2020). Each component team was free to  
8 work in idiosyncratic ways, resulting in variant norms and routines across teams that needed  
9 coordination and integration to yield a system-level work product. In addition, a goal hierarchy  
10 existed; each component team needed to build its own machine, but also coordinate with other  
11 teams to achieve the superordinate goal of building a system-level machine. Reinforcing the goal  
12 hierarchy, students' performance in the course was both a function of the performance of their  
13 component team's machine and the performance of their section's integrated machine.

32

### 33 **Sample and Data Sources**

34 We collected data from 44 MTSs, which were composed of 295 teams and 930  
35 individuals. Teams comprised either three or four members (Mean = 3.15, SD = 0.46) and the  
36 MTSs consisted of between four and eight teams (Mean = 6.70, SD = 1.11). Participants were,  
37 on average, 19 years old (SD = 1.68). The sample was predominantly male (76%) and  
38 represented a range of ethnicities (59% White, 25% Asian, 6% Hispanic or Latino, 5% multi-  
39 ethnic, 4% Black or African American, and 1% Native Hawaiian or Pacific Islander).  
40  
41  
42  
43  
44  
45  
46  
47  
48

49 To guard against single source and single method limitations (e.g., Podsakoff,  
50 MacKenzie, Lee, & Podsakoff, 2003), we collected data in three ways. First, we used self-report  
51 surveys to collect background information during week 1 and to assess team conflict during  
52 week 8. At each time, participants received an email inviting them to complete a web-based  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 survey. We received 913 completed responses to the first survey (98% overall response rate,  
4 100% median team-level response rate) and 827 responses to the second survey (89% overall  
5 response rate, 100% median team-level response rate). Second, we used wearable sensors to  
6 measure how often participants interacted with one another. In total, 912 participants (98%  
7 overall participation rate, 100% median team-level participation rate) wore a sensor during  
8 weeks 5, 6, and 7. Third, we used trained observers to assess the performance of the Rube  
9 Goldberg machines, which were evaluated at the team and system levels in week 11. Figure 2B  
10 visually arrays these data collection sources and timings. The findings that we report in this  
11 paper were part of a larger data collection designed for pedagogical purposes and to provide  
12 individual feedback to students. One other paper (Graham, Mawritz, Dust, Greenbaum, &  
13 Ziegert, 2019) has also used one variable (individual dominance orientation) from this same data  
14 collection effort. Some participants from the data collection effort were participants in a different  
15 study six months later; Graham et al. (2019) used data on students' individual dominance  
16 orientation as a baseline assessment. Although there was a minor overlap in participants, there  
17 are no overlaps in variables used in this paper and Graham et al. (2019).

## 37 **Measures**

38  
39 *Interpersonal interactions.* We operationalized interpersonal interactions as the amount  
40 of time that individuals spent in relative physical proximity to one another, as assessed using  
41 wearable Bluetooth sensors. Proximity is a medium through which coordination-focused  
42 interactions often occur in organizations (Okhuysen & Bechky, 2009). Undergirding this idea is  
43 the premise that if two people are physically close to one another, they are likely to be engaged  
44 in an interpersonal interaction with one another (Bernstein & Turban, 2018; Ingram & Morris,  
45 2007; Müeller, Meneses, Humbert, & Guenther, 2020). Substantiating this premise, research has  
46 repeatedly found that proximity is a valid measure of interpersonal interaction and collaboration  
47

in field-based settings (e.g., Chaffin et al., 2017; Kraut, Egido, & Galeghar, 2014; Matusik, Heidl, Hollenbeck, Yu, Lee, & Howe, 2019; Müller et al., 2020; Parrino, 2015). Of particular relevance for our measurement approach, researchers have used wearable Bluetooth sensors and examined the relation between their measurement of physical proximity and self-report survey measures of interpersonal interactions (e.g., advice giving/receiving, friendship), finding support for convergent validity (Matusik et al., 2019; Müller et al., 2020).

Nonetheless, because proximity assessed using Bluetooth sensors does not consider people's orientation toward one another (e.g., whether they are face-to-face or back-to-back), we recognize that it is possible for two people to be physically close, but not engaged in an interpersonal interaction. It is also possible for two people to be physically distant and engaged in an interaction through technology (e.g., texting, phone calls, web conferencing). Each of these possibilities, as sources of measurement error, would reduce statistical power and result in more conservative tests of our hypotheses (Schwab, 1980). Given Matusik et al.'s (2019) and Müller et al.'s (2020) guidance to understand contextual nuances that might influence the validity of proximity-based measures from Bluetooth sensors, we observed all 44 MTSs in our study for at least two hours during weeks 1-3 of the project. In these observations, we sought to scrutinize the use of physical proximity as a reasonable indicator of work-related interpersonal interactions within the specific context of our research. Our observations indicated that proximity did indeed correspond with meaningful interactions in this context. When participants varied their physical location—either moving toward teammates at their workstation or toward members of other teams—it was because they sought to examine or inquire about others' work. Participants in our context did not rely upon digital means to interact—their colocation in the same classroom each week rendered in-person interactions the easiest means of communicating with each other.

1  
2  
3 We assessed interpersonal interactions during weeks 5, 6, and 7. We chose these weeks  
4 because they comprised the action phase when teams were responsible for building their  
5 component machines and designing mechanisms for transferring energy between teams. Given  
6 prior theory and research regarding the benefits and costs of informal coordination (e.g., Kanfer  
7 & Kerry, 2012; Mathieu et al., 2018), it is during this phase when we expected the relations that  
8 we hypothesized to be most salient (Rico et al., 2017). Further, boundary spanning activities are  
9 most likely to occur and have the greatest impact during this MTS action phase (Choi, 2002;  
10 DeChurch & Marks, 2006; DeChurch, Burke, Shuffler, Lyons, Doty, & Salas, 2011). This action  
11 phase—before the MTSs in our study shifted in week 8 to an outcome phase to start system-wide  
12 testing of the machines (Marks, Mathieu, & Zaccaro, 2001; Rico et al., 2017)—thus constituted  
13 the right time for assessing informal interactions (Mitchell & James, 2001).

28 We recorded physical closeness using wearable multi-sensor devices (i.e., Kim, McFee,  
29 Olguin, Waber, & Pentland, 2012). Following recent validation studies (Chaffin et al., 2017;  
30 Matusik et al., 2019; Müller et al., 2020), we used the raw Bluetooth signal strength values  
31 recorded by the sensors to assess the time that members interacting with one another. Bluetooth  
32 devices regularly scan the environment (e.g., every 25 seconds) to determine whether other  
33 devices are available for connection. When one device detects a second device, it records the  
34 strength of the connection between the two devices, called the RSSI value, at that moment.  
35 Although signal strength can be influenced by other factors (e.g., walls made of different  
36 materials), validation studies have found that variations in RSSI values correspond to variations  
37 in the proximity of two Bluetooth devices; the higher an RSSI value, the closer in physical space  
38 the two devices are likely to be (Matusik et al., 2019; Müller et al., 2020).

53 To measure intrateam and inter-team interactions, we aggregated the markers of  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 physically proximal interactions between two people to the team level. For intrateam  
4  
5 interactions, we calculated the number of dyadic interactions detected by the sensors among  
6  
7 members within the same component team. Based on the devices' regular and periodic scan for  
8  
9 other devices, this indicates the amount of time that the members of a given team were engaged  
10  
11 with others in their own team. To measure inter-team interactions, we calculated the number of  
12  
13 dyadic interactions that the sensors detected between the members of one component team and  
14  
15 the members of other teams in the MTS. This indicates the time the members of one team were  
16  
17 engaged in interpersonal interactions with others who were outside their team. To test our  
18  
19 system-level hypothesis, we used the system-level mean (i.e., across teams) of these team-level  
20  
21 measures. Appendix A details the steps we took to measure interpersonal interactions using the  
22  
23 raw values obtained from the sensors. Appendix B reports the results of sensitivity analyses,  
24  
25 which examine and support the robustness of our findings to operationalizing interactions using  
26  
27 different signal strength values when processing the raw Bluetooth detection information.

31

32  
33 ***Team conflict.*** During week 8, participants completed Jehn and Mannix's (2001) 9-item  
34  
35 measure of team conflict using a 7-point scale, with anchors of 1 = *Never* to 7 = *All the time*. A  
36  
37 sample item is "How often are there disagreements about who should do what in your work  
38  
39 group?"<sup>1</sup> We measured conflict in week 8 because this is when team members had worked  
40  
41 through the goal striving process and action phase that theory suggests engender conflict (Marks  
42  
43 et al., 2001; Rico et al., 2017). This is also the time when conflict may be particularly detrimental  
44  
45  
46  
47  
48

---

49  
50 <sup>1</sup> This measure comprises three items each for task, process, and relationship conflict. Like other  
51  
52 field studies of conflict (e.g., Bunderson, van der Vegt, Cantimur, & Rink, 2016; O'Neill,  
53  
54 McLarnon, Hoffart, Woodley, & Allen, 2018), we found high, positive correlations among these  
55  
56 three forms of conflict (Mean correlation = 0.70). Although confirmatory factor analyses showed  
57  
58 that a three-factor model was better than a one factor model ( $\Delta\chi^2 = 569.22, p < 0.01$ ), our results  
59  
60 were substantively the same across the three different forms of conflict. To present our results  
parsimoniously, we report results for the single overall measure of team conflict.

1  
2  
3 to team effectiveness (Jehn & Mannix, 2001). The measure instructed members to rate conflict  
4 behaviors in the team agnostic of a specific timeframe to allow for members to reflect back over  
5 the entirety of the preceding action phase. We found high team-level interitem reliability ( $\alpha =$   
6 0.94) and justification for aggregation to the team level [Median  $r_{wg(j)} = 0.91$ ; ICC(1) = 0.21,  $p <$   
7 0.01; ICC(2) = 0.43] (Bliese, 2000). The relatively low ICC(2) is due to the small size of the  
8 component teams consisting of three to four members (Bliese, 2000).  
9

10  
11

15  
16  
17 **Team performance.** Instructors informed teams in the first week of the course that team  
18 performance would be assessed as the percentage of successful energy transfers across the events  
19 within their Rube Goldberg machine. A transfer was considered successful when energy passed  
20 seamlessly from one event to the next within the same team's Rube Goldberg machine without  
21 any manual intervention by team members. Trained observers measured component teams'  
22 performance across five trial runs of the machines conducted in week 11. We calculated team  
23 performance as the total percentage of successful within-team energy transfers across the five  
24 performance trials. Component team performance ranged from 16.67% to 100%.

26  
27  
28  
29  
30  
31  
32  
33  
34

35  
36 **System performance.** Trained observers measured system performance as the rate of  
37 successful energy transfers between component teams' machines in the system. Between-team  
38 energy transfers represents the successful execution of the MTS's tasks between adjacent teams  
39 in the sequentially interdependent MTS (Rico et al., 2018). To successfully transfer energy from  
40 one team to the next, adjacent teams had to determine the precise location in three-dimensional  
41 space (i.e., length, width, height) of where the transfer would occur and the means of the transfer  
42 (e.g., a marble rolling down a ramp from one team to another). This measure of system  
43 performance also included the final event of transferring sugar to a cup of coffee. As with team  
44 performance, we calculated system performance across the five performance trials conducted in  
45

2  
3 week 11; its range was 73.33% to 100%.  
4

5           **Controls.** We used a theoretically driven approach to select controls for inclusion in our  
6 models (Becker, Atinc, Breaugh, Carlson, Edwards, & Spector, 2016). In predicting team  
7 conflict and team performance, we controlled for team familiarity (i.e., degree to which team  
8 members knew one another at the start of the project) and team size (i.e., the number of people  
9 on the team roster). We controlled for team familiarity because teams with familiar members  
10 may experience less conflict and perform at a higher level than teams of unfamiliar members  
11 (e.g., Huckman, Staats, & Upton, 2009). We assessed familiarity using a round robin survey item  
12 during week 1 (i.e., “I know this team member well” using a 7-point agreement scale) and used  
13 the mean across these dyadic ratings to operationalize team-level familiarity as an additive  
14 construct (Chan, 1998). We controlled for team size because larger teams possess more resources  
15 than smaller teams and, as a result, might be better equipped to perform at a high level by design  
16 (e.g., Thomas & Fink, 1963). In predicting system-level performance, we controlled for the  
17 number of teams in the MTS, as larger systems introduce the potential for greater complexity  
18 (Shuffler & Carter, 2018). We also controlled for average team familiarity, team performance,  
19 and team conflict when predicting system-level performance. We controlled for these variables  
20 to focus specifically on system performance over and above team-level dynamics.<sup>2</sup>

#### 42 **Analyses**

43           Central to our model is the idea that the benefits of informal coordination mechanisms are  
44 a function of how well MTS members balance their intrateam and inter-team interactions. That  
45 is, the balance of interactions, irrespective of the amount of interactions, shapes team conflict,  
46  
47  
48  
49  
50  
51  
52

---

53  
54 <sup>2</sup> In subsequent sensitivity analyses, we also examined additional controls of the number of  
55 people in each MTS and the performance of the lowest performing team. The significance and  
56 approximate magnitude of the focal parameter estimates for our hypothesis tests were equivalent.  
57  
58  
59  
60

1  
2  
3 team effectiveness, and system effectiveness. To test this idea, we used polynomial regression  
4 with response surface analysis (Barranti, Carlson, & Côté, 2007; Edwards, 1994; Edwards &  
5 Parry, 1993). Whereas traditional approaches—such as using a difference score or creating a  
6 product term between two variables—are conceptually intuitive, these approaches are limited in  
7 two important ways (Edwards, 1994, 1995, 2001; Edwards & Parry, 1993). First, interpreting  
8 statistical tests of balance effects using these simpler approaches rests upon assumptions about  
9 the form of the relation among the variables that could lead to erroneous interpretations  
10 (Edwards, 2001). Second, in contrast to the coarse view of balance effects afforded by simpler  
11 approaches, polynomial regression and response surface analysis afford the ability to examine  
12 the specific form of balance effects on a criterion variable (Edwards & Parry, 1993). Response  
13 surface analysis involves plotting and testing the parameters from a polynomial regression model  
14 to determine the shape of the relationship between the congruence and incongruence of two  
15 variables and an outcome. This is important because our first hypothesis specifies that excessive  
16 inter-team interactions relative to intrateam interactions enhances conflict.

31  
32  
33  
34

35 We tested our hypotheses using a subsample of the 295 teams comprising the 44 multi-  
36 team systems. Wearable device hardware or system failures, similar to those documented by  
37 other researchers (e.g., Chaffin et al., 2017; Matusik et al., 2019), necessitated excluding 22  
38 teams for which we lacked data on interpersonal interactions. We also excluded 5 teams that  
39 were outliers in measures of interpersonal interactions (i.e., greater than three SD above the  
40 mean). We excluded these teams because we suspected invalid measurement of interactions;  
41 specifically, the sensor data from these teams suggests that participants removed their devices  
42 and placed them in a common physical location (Müller et al., 2020). Including these 5 teams in  
43 our hypothesis tests does not change the magnitude or significance of the focal parameters for

3 testing our hypotheses. More broadly, the 27 teams that we excluded did not differ significantly  
4 from the remaining 268 teams with respect to team size, familiarity, conflict, or performance.  
5  
6

7  
8 Our hypotheses consider relationships at two levels of analysis—the team level and the  
9 system level. Because teams are nested within systems, the team-level observations of any given  
10 system are non-independent, which violates the assumption of independence that underlies the  
11 calculation of standard errors in OLS regression. To address this in our analyses predicting team  
12 conflict and team performance, we used clustered standard errors to adjust for potential inflation  
13 due to non-independence (McNeish, Stapleton, & Silverman, 2017).

32 Hypothesis 1 predicted that imbalance between intrateam and inter-team interpersonal  
33 interactions relates to component team conflict. Specifically, we argued that an excess in inter-  
34 team interactions, relative to intrateam interactions, increases team conflict. Models 3 and 4 of  
35 Table 3 provide the results of polynomial regression analyses used to test Hypothesis 1. Model 3  
36 includes controls for team size and team familiarity; Model 4 shows the robustness of the results  
37 when excluding these controls. Following Barranti et al. (2017), we calculated four simple slope  
38 parameters ( $a_1$ ,  $a_2$ ,  $a_3$ , and  $a_4$ ) that, together, reflect the shape of the three-dimensional response  
39 surface plot depicted in Figure 3A. Although all four parameters must be interpreted together, of  
40 particular relevance for testing Hypothesis 1 is the  $a_3$  parameter, which reflects the slope of the  
41 line of incongruence. As Model 3 and Figure 3A show, this parameter was significant and  
42 negative ( $a_3 = -0.32$ ,  $p < 0.01$ ) supporting Hypothesis 1, indicating that team conflict increases

10 Hypothesis 2 predicted that the imbalance effect of intrateam and inter-team interactions  
11 indirectly relates to team performance through team conflict. Table 4 provides the results of  
12 regression analyses predicting component team performance. As shown in Model 5 of Table 4,  
13 there was a significant negative relation between team conflict and team performance ( $B = -0.02$ ,  
14  $p < 0.01$ ). However, there were no significant effects of interpersonal interactions on team  
15 performance. This suggests that the relationship between interpersonal interactions and team  
16 performance is indirect, passing through team conflict. To test this indirect effect, we used a  
17 block variable approach, with bootstrapped standard errors, in which we created weighted linear  
18 composites of the five polynomial estimates on team conflict and performance (Edwards &  
19 Cable, 2009). We then estimated a path model and computed the indirect effect of the block  
20 variables on team performance through team conflict. Supporting Hypothesis 2, we found that  
21 the indirect effect of imbalance of intrateam and inter-team interactions on team performance,  
22 through team conflict, was significant ( $B = -0.02$ ,  $SE = 0.01$ ,  $p < 0.05$ ,  $\beta = -0.04$ ).

40 At the system-level, Hypothesis 3 predicted that—above and beyond component team  
41 conflict and performance—imbalance between intrateam and inter-team interactions is  
42 negatively related to system performance. Table 5 presents the results of regression analyses  
43 predicting system-level performance. As seen in Model 3 of Table 5, and depicted in Figure 3B,  
44 the relationship between interpersonal interactions and system performance was curvilinear.  
45 Directly relevant to testing Hypothesis 3, based on the significant downward curvature along the  
46 line of incongruence, we found that system performance was higher when team members

3 balanced their engagement in interpersonal interactions with the members of their own  
4  
5 component team and the members of other component teams in the MTS ( $a_4 = -0.07, p < 0.05$ ).  
6  
7 As members disproportionately engaged in intrateam or inter-team interactions, resulting in an  
8  
9 imbalance, system performance declined. Therefore, Hypothesis 3 was supported.

### 16 17 **Post Hoc Examinations: Leveraging the Granularity of Data from Wearable Sensors**

18 Following Hollenbeck and Wright (2017), who encouraged researchers to report the  
19 findings of post hoc analyses, we sought to extend the findings reported above by leveraging the  
20 granularity of our sensor data to gain further insights into informal coordination in MTSs. As an  
21 overarching structure for this effort, we drew from Mathieu et al. (2018), who organized research  
22 on coordination in MTSs as considering functions, foci, forms, and phases. Our hypotheses  
23 considered how interpersonal interactions are an informal coordination mechanism in MTSs—  
24 that is, we examined the function of interpersonal interactions. Informed by our results, we  
25 developed post hoc predictions and conducted analyses examining how differing foci of  
26 interactions (i.e., the specific targets of informal coordination) and differing forms of interactions  
27 (i.e., the structure of who is interacting with whom) relate to MTS effectiveness. While these  
28 analyses allow for a richer examination of informal coordination with foci and forms  
29 complementing functions, the sensor data, which we collected during a single period of the  
30 project, did not permit examining the phases component of Mathieu et al.'s (2018) framework.

49 ***Examining different coordination foci.*** Mathieu et al. (2018) referred to the different  
50 targets of coordination efforts in an MTS as foci. Our hypotheses differentiated between two  
51 broad foci—intrateam interactions and inter-team interactions. However, the sequential nature of  
52 the project completed by the MTSs in our study may render some inter-team interactions more  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 important for MTS effectiveness than others. As Figure 2A depicts, teams that are adjacent to  
4 one another in the MTSs that we studied (e.g., team 3 with adjacent teams 2 and 4) must directly  
5 integrate their machines for the system to function. Building from Rico et al.'s (2018)  
6 framework, and our findings on the function of interpersonal interactions, we might expect that  
7 informal interactions between adjacent teams are more important than interactions between non-  
8 adjacent teams (e.g., team 3 with non-adjacent team 5). Rico et al. (2018) highlighted the need  
9 for explicit coordination processes, such as direct communication and interactions, for how work  
10 activities between teams “fit together” (Rico et al., 2018: 337), which may be especially valuable  
11 for adjacent teams due to sequential interdependence. We therefore suggest that interpersonal  
12 interactions are particularly beneficial to team and MTS success when the inter-team foci are  
13 adjacent teams compared to non-adjacent teams.

28 To examine whether the imbalance effects that we hypothesized differ depending on  
29 whether teams are proximal in the flow of work, we assessed how much members interacted with  
30 the members of adjacent versus non-adjacent teams. Using sensor data, we calculated adjacent  
31 and non-adjacent inter-team interactions by aggregating dyadic interactions among MTS  
32 members according to the same approach previously described for inter-team interactions. We  
33 demarcated whether a given interaction comprised the members of teams that were next to one  
34 another in the MTS (i.e., adjacent inter-team interactions) versus teams that were separated by at  
35 least one other team (i.e., non-adjacent inter-team interactions). Using this distinction, we re-ran  
36 Model 3 from Table 3, predicting team conflict separately for adjacent and non-adjacent inter-  
37 team interactions. Similar to our a priori findings, we observed an imbalance effect for non-  
38 adjacent inter-team interactions ( $a_3 = -0.34$ ,  $SE = 0.08$ ,  $p < 0.01$ ). As imbalance increased, with  
39 inter-team interactions with non-adjacent teams exceeding intrateam interactions, team conflict

1  
2  
3 increased. The imbalance effect was negative but non-significant, however, for interactions with  
4 adjacent teams ( $a_3 = -0.12$ ,  $SE = 0.10$ ,  $p > 0.10$ ). Conflict did not significantly rise as inter-team  
5 interactions with adjacent teams exceeded intrateam interactions. At the system-level, we re-ran  
6 Model 3 from Table 5, predicting system performance separately for adjacent and non-adjacent  
7 interactions. Like the team-level, the imbalance effect differed for these two types of inter-team  
8 interactions. The imbalance of non-adjacent inter-team and intrateam interactions was significant  
9 and negatively related to system performance ( $a_4 = -0.06$ ,  $SE = 0.03$ ,  $p < 0.05$ ). The effect was  
10 not significant, however, for adjacent inter-team interactions ( $a_4 = -0.06$ ,  $SE = 0.05$ ,  $p > 0.10$ ).  
11 Taken together, these post hoc findings suggest that it is important for researchers to consider the  
12 specific foci of informal coordination. The detrimental effects of imbalance that we reported in  
13 our hypothesis tests are especially pronounced when the interpersonal inter-team interactions are  
14 with non-adjacent teams with which the focal team does not directly integrate in the system.

31 ***Examining different coordination forms.*** Mathieu et al. (2018: 338) used the term form  
32 to describe “the structure (e.g., boundary spanners, members, centralized, decentralized) of who  
33 in the MTS enacts the coordination functions.” In our hypotheses, we considered inter-team  
34 interactions agnostic to whether they were broadly distributed across team members—such that  
35 all members engaged in similar amounts of interactions with those outside the team—or  
36 concentrated in a single member. Although some MTS research suggests that inter-team  
37 interactions are best accomplished by a formally designated liaison (e.g., Davison et al., 2012),  
38 other MTS findings indicate that teams may benefit from having several members engage in  
39 these activities (e.g., DeChurch & Marks, 2006; Mell et al., 2020). This ambiguity is further  
40 reflected in the boundary spanning literature, in which the question of whether external  
41 interactions are “best reserved for only a single team member or leader...” remains unresolved

1  
2  
3 (Marrone, 2010: 931).  
4

5           Given these differing possibilities, we leveraged our sensor data to examine coordination  
6 forms as the concentration of inter-team interactions in a component team—the degree to which  
7 a team channeled inter-team interactions through a subset of team members—might influence the  
8 functional value of informal interactions. To do so, for each MTS member we first pooled the  
9 dyadic inter-team interactions of that individual to create a measure of how much they interacted  
10 with the members of other teams. Then, we calculated the coefficient of variation for each  
11 team—a metric that captures concentration in terms of how much more a person engages in  
12 inter-team interactions compared to the other members of their team (Harrison & Klein, 2007).

15  
16  
17  
18  
19  
20  
21  
22  
23

24           To examine the effect of the form of informal coordination, we replaced the general  
25 measure of inter-team interactions with this measure of concentration and re-ran Model 2 from  
26 Table 3 to predict team conflict. Consistent with our earlier results, which did not consider  
27 concentration, we found that intrateam interactions were significantly negatively related to team  
28 conflict ( $B = -0.26$ ,  $SE = 0.11$ ,  $p < 0.05$ ). Although the coefficient was negative, concentration of  
29 inter-team interactions was not significantly related to team conflict ( $B = -0.10$ ,  $SE = 0.18$ ,  $p >$   
30  $0.10$ ). Also at the team level, we re-ran Model 2 from Table 4, predicting team performance by  
31 replacing inter-team interactions with concentration. There was a positive relationship between  
32 concentration of inter-team interactions and team performance ( $B = 0.04$ ,  $SE = 0.02$ ,  $p = 0.05$ ).  
33 Teams where inter-team interactions were more concentrated in a single member, as opposed to  
34 more equally distributed across members, performed better. These findings suggest that the form  
35 of coordination does not influence team conflict; however, concentrating boundary spanning  
36 efforts could have direct benefits for the performance of teams embedded within an MTS.

1  
2  
3 might influence system-level performance by re-running Model 2 of Table 5, but substituting the  
4 inter-team interactions measure with the system-level mean of concentration of inter-team  
5 interactions. The general tendency for teams to concentrate their inter-team interactions was not  
6 related to system-level performance ( $B = -0.07$ ,  $SE = 0.05$ ,  $p > 0.10$ ), controlling for component  
7 team performance. Finally, to examine the robustness of the results of our a priori hypothesis to  
8 concentration, we included this concentration measure as a control variable in our prior analyses.  
9  
10 The hypothesis test results were robust to the inclusion of concentration in the models. These  
11 post hoc analyses with regard to the form of informal coordination suggest that concentrating  
12 inter-team interactions within a subset of team members may have benefits for team performance  
13 that are not transmitted through team conflict. Moreover, these benefits do not seem to come at  
14 the cost of system performance.

## 28 **DISCUSSION**

29  
30 Because of their unique properties—including hierarchically nested goals and structural  
31 differentiation—MTSs face unique coordination challenges (DeChurch & Marks, 2006; Zaccaro  
32 et al., 2020). Findings from our study resolve conceptual and empirical ambiguities regarding  
33 how informal mechanisms enable or inhibit coordination, and thus influence MTS team and  
34 system effectiveness. Our conceptual model and empirical findings reveal that interpersonal  
35 interactions between the members of different component teams must be accompanied by a  
36 balanced amount of internally-focused interactions among members of the same team for an  
37 MTS to benefit from informal interactions. This has implications for MTS theory and practice.

### 49 **Theoretical Contributions and Implications for Future Research**

50 Our research suggests that the pessimistic views about informal mechanisms in past MTS  
51 scholarship (e.g., Lanaj et al., 2013)—compounded by ambiguous past empirical findings (e.g.,  
52 Davison et al., 2012; Mell et al., 2020)—may have undersold the potential utility for informal  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 coordination to help MTS members overcome their unique challenges. Past empirical research  
4 on MTSs, which has considered the use of informal mechanisms within and between teams as  
5 independent factors, indicates that informal coordination can be both detrimental (Davison et al.,  
6 2012) as well as beneficial (Mell et al., 2020) to MTS functioning. By integrating insights from  
7 the boundary spanning literature, we proposed that it is necessary to consider informal  
8 mechanisms within and between teams in concert, rather than as independent factors. The core  
9 insight that emerges from our research is that balance—manifested in the correspondence of  
10 intrateam and inter-team interactions—serves a beneficial coordination function that enables  
11 effectiveness at both the team and system levels in MTSs.  
12

15  
16  
17  
18  
19  
20  
21  
22  
23

24         At the team level, balanced interactions reduce the occurrence of team conflict, which,  
25 we find, undermines component team performance. Conflict is most likely to emerge, and detract  
26 from performance, when a component team engages in inter-team interactions that exceed  
27 intrateam interactions. Our conceptual model and findings also indicate that balanced  
28 interpersonal interactions serve a valuable coordination function at the system level. MTS  
29 effectiveness is highest when inter-team interactions, which our theory suggests help to integrate  
30 activities across teams, are accompanied by corresponding and similar levels of intrateam  
31 interactions, which we argue enable team members to adjust their local activities in response to  
32 external information. Although these ideas align with past boundary spanning theory (e.g., Choi,  
33 2002), we did not directly measure system-level knowledge transfer mechanisms. As such, future  
34 research is needed to document precisely how informal interactions shape the flow of  
35 information, between and within teams, in MTSs.  
36

49  
50

51         Our findings regarding balance reinforce the need to jointly consider effects at the team  
52 and system levels to more fully understand how to navigate inherent coordination challenges  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 within MTSs. The idea of a “performance tension” in MTSs—a tension between component  
4 teams and the overarching system—is a common thread running throughout the MTS literature  
5 (e.g., Luciano et al., 2018). Yet, only a handful of MTS studies have separately conceptualized  
6 and tested performance effects at the team and system levels of analysis (e.g., DeChurch &  
7 Marks, 2006; Mell et al., 2020). Building from the boundary spanning literature and the need for  
8 balance, our findings indicate that MTS members can neither maximize on within-team  
9 coordination or on between-team coordination to realize their objectives. Instead, the side-by-  
10 side comparison of effects at the team and system levels in Figure 3 illustrates the need for  
11 balanced interpersonal interactions in MTSs. Teams in the region of Figure 3A that overly  
12 emphasize inter-team interactions have elevated levels of team conflict, which is related to lower  
13 levels of team performance. However, acting to minimize component team conflict by focusing  
14 entirely on intrateam interactions is not the answer within the unique context of MTSs. As Figure  
15 3B illustrates, there are major consequences for system-level performance when teams engage in  
16 an incongruent pattern of informal interpersonal interactions. Instead, to address the tension for  
17 simultaneously achieving team-level and system-level performance, MTS members should seek  
18 balance to integrate inter-team interactions with corresponding intrateam interactions.

36  
37  
38  
39  
40 The findings of our post hoc analyses, however, suggested that this interplay between the  
41 team and the system, and their underlying mechanisms, may be even more nuanced than we  
42 initially proposed. Rather than treating other component teams as a singular and undifferentiated  
43 external focus of coordination efforts, we found that that it is useful to differentiate the foci of  
44 interaction patterns and coordination efforts between external teams based on the level of direct  
45 interdependence. These findings could also point to the potential value of both formal and  
46 informal coordination mechanisms for MTSs—at the very least for the kind of sequential MTSs  
47

1  
2  
3 that we studied. Formal coordination mechanisms, such as planning or training, could focus MTS  
4 members' informal coordination efforts specifically on those linked teams (i.e., teams adjacent in  
5 the workflow) with whom mutual adjustments are most likely to be needed for system level  
6 success. Recognizing that our findings regarding adjacent and non-adjacent teams were post hoc,  
7 further research is needed to better understand this distinction.  
8  
9

10  
11  
12 To be clear, although we find that informal mechanisms serve an important coordination  
13 function in MTSs, our work does not call into question the value of formal mechanisms or test  
14 the relative benefits of informal versus formal mechanisms for enabling coordination in MTSs.  
15 Indeed, several prior MTS studies have directly tested and found positive effects of a range of  
16 formal mechanisms for enabling coordination (Zaccaro et al., 2020). The purpose of our research  
17 was to resolve ambiguity about whether informal mechanisms could also serve a valuable  
18 coordination function within MTSs, as identified by both classic coordination theorists (e.g., Van  
19 de Ven et al., 1976) and scholars who study knowledge-based teams (e.g., Faraj & Sproull,  
20 2000). Considering our findings alongside research that has examined formal mechanisms,  
21 though, highlights a particularly promising direction for future MTS research: studying the  
22 intersection of formal and informal mechanisms of coordination. Because formal and informal  
23 mechanisms are not mutually exclusive (Katz & Kahn, 1978; March & Simon, 1958), they could  
24 function together in additive, synergistic, or even incompatible ways. For example, it is possible  
25 that informal interactions enable a well-defined structure and role system to adapt to unexpected  
26 events or cope with a transient workforce. Research on organizations that face related  
27 coordination challenges hints at the value of adopting semi-structured mechanisms—ones that  
28 are neither exclusively formal nor exclusively informal (e.g., Bechky, 2006; Bechky &  
29 Okhuysen, 2011; Bierly & Spender, 1995; Brown & Eisenhardt, 1997). Considering our post hoc

1  
2  
3 findings on coordination forms and the potential value for component teams, but not systems, of  
4 concentrating informal interactions, such semi-structured approaches may provide agility that  
5 helps MTSs respond to coordination challenges. It is also possible, though, that an excessive  
6 reliance on informal interactions could dilute the efficiency and clarity of formal design and  
7 planning, contributing to breakdowns. Future research is needed to answer these questions.  
8  
9

10  
11  
12  
13  
14  
15 Finally, while our findings highlight the importance of balance, we did observe some  
16 indication that it may also be important to consider the absolute level of members' interactions  
17 with one another. In particular, the  $a_2$  parameter in Model 3 of Table 5, which indicates how the  
18 effect of balance changes across different levels of corresponding intrateam and inter-team  
19 interactions, approached significance for system performance. As depicted in Figure 3B, this  
20 inverted-U shaped relationship suggests that, when balanced, increasing levels of intra- and inter-  
21 team interactions are valuable for system performance until an inflection point is reached  
22 whereby additional interactions begin to detract from system performance. Examining the  
23 volume of informal interactions could thus be a useful avenue for future MTS research.

### 35 **Practical Implications**

36  
37 Our findings have actionable implications for organizations, given the nature of  
38 interdependence within and across teams in MTSs. Although the variance in performance across  
39 MTSs may be small, as was the case in our study, errors committed by any one component team  
40 can ripple throughout and undermine the entire system. A failure of one team can cause the  
41 entire system to fail given the interdependent nature of MTSs (Zaccaro et al., 2020). Moreover,  
42 the costs of coordination breakdowns in MTSs can be extraordinary. NASA, for example,  
43 suffered hundreds of millions of dollars in losses due to coordination breakdowns in an MTS  
44 working on the Mars Climate Orbiter (Shuffler & Carter, 2018). Our results speak to the benefits  
45 of effectively balancing intrateam and inter-team interactions to achieve coordination and avoid  
46

56  
57  
58  
59  
60

1  
2  
3 such costly errors, especially in MTSs focused on knowledge work. The operationalization of  
4 performance in our study—the reliability of a machine—closely parallels the kinds of metrics  
5 that many knowledge-based MTSs (e.g., software development, mechanical engineering, etc.)  
6 rely on to assess the quality of their work. Conversely, the inverse of this measure—the error or  
7 defect rate of a machine—has implications for the avoidable costs that organizations seek to  
8 minimize as defects compound across levels (Lei, Naveh, & Novikov, 2016). One error within or  
9 between teams can ripple through and destabilize the overall MTS.  
10  
11  
12  
13  
14  
15  
16  
17  
18

19 Our results suggest that the benefits of effectively balancing informal interactions could  
20 be substantial given the downstream impact of focusing too much on either intrateam or inter-  
21 team interactions. For each additional point of team conflict, the error rate for the component  
22 teams' machines increases by approximately 2%. At the system-level, imbalanced systems can  
23 have error rates approximately twice as high in comparisons to systems that balance intra- and  
24 inter-team interpersonal interactions. This difference is practically meaningful as even a 2%  
25 reduction in a product's defect rate is consequential for a modern knowledge-based MTS  
26 (Goodman, Ramanujam, Carroll, Edmondson, Hofmann, & Sutcliffe, 2011). Thus, although the  
27 variance explained in our analyses may seem relatively small, our findings regarding the need for  
28 MTS members to balance their interactions still offer consequential managerial insights.  
29  
30  
31  
32  
33  
34  
35  
36  
37  
38  
39  
40  
41

42 Given this importance of balance for MTS functioning and performance, our findings  
43 indicate that MTS coordination efforts are aided when leaders and members consciously manage  
44 interpersonal interactions with regard to who they interact with and how much time they devote  
45 internally and externally. While inter-team interactions are necessary for coordinating across  
46 teams, team members need to ensure that these external interactions are coupled with at least a  
47 similar level of intrateam interactions to integrate new information within a team. Our post hoc  
48  
49

1  
2  
3 analyses further suggest that members should focus these external interactions with members of  
4 those teams they integrate directly with in the system. In addition, teams but not systems may  
5 benefit from concentrating these boundary spanning efforts in a subset of team members. Social  
6 network analysis is one practical tool that may aid MTS managers in monitoring and altering  
7 informal interactions within and between teams so that they are kept in balance (e.g., Leonardi &  
8 Contractor, 2018). Tools for tracking employee interactions through email, chat, and  
9 asynchronous messages could be specifically deployed to help MTS members maintain an  
10 appropriate balance in their informal interactions.

### 21 **Limitations**

22  
23 Our work has limitations due to the research context and sample. Given the nature of  
24 sequential MTSs, the workflow is from one team to another in a linear fashion; however, the  
25 interactions between adjacent teams are also reciprocal in that adjacent teams need to coordinate  
26 between each other for successful handoffs and transfers (Rico et al., 2018). As such, our results  
27 are generally limited to this type of MTS structure and more research is needed to determine how  
28 they generalize to other types of structures such as intensive forms of interdependence (Rico et  
29 al., 2018). Further, we examined a sample of students studying to become engineers in a U.S.  
30 University, which may limit the generalizability of our findings to organizations as well as cross  
31 cultural contexts. However, this sample allowed multiple forms of measurement (sensors,  
32 surveys, and observations) across multiple time points, and also provided a standardized task  
33 across multiple MTSs that enhanced internal validity (DeChurch & Marks, 2006). These benefits  
34 have similarly been noted in prior MTS research using targeted samples such as Air Force  
35 trainees completing a simulation (e.g., Davison et al., 2012) or undergraduate students  
36 completing a simulation (Porck et al., 2019). Further, the sample enabled us to examine the  
37 implications of interpersonal interactions within larger MTSs than prior studies, which have  
38

57  
58  
59  
60

1  
2  
3 tended to focus on smaller systems of two or three component teams. While our sample contains  
4  
5 a comparatively larger number of teams per system (nearly 7 teams on average) relative to prior  
6  
7 quantitative research, the system-level sample size of 44 limits statistical power in our statistical  
8  
9 analyses. Finally, the task structure enabled us to model interdependencies characteristic of  
10  
11 MTSs, including a goal hierarchy and structural differentiation. Nonetheless, the generalizability  
12  
13 of this task is unclear. Future research should examine informal coordination in other cultural  
14  
15 contexts, organizational contexts, and in larger samples to better understand their role in MTSs.  
16  
17  
18

19           While we believe sensors are an advantageous way to assess interpersonal interactions,  
20  
21 there are several potential limitations with this approach. In particular, we operationalized  
22  
23 interaction as a quantity of time spent in close physical proximity. However, we could not assess  
24  
25 the quality of the interactions among MTS members, nor were we able to measure the content of  
26  
27 team members' interactions. Supplementing a quantity-based approach with a quality and  
28  
29 content focus would further elucidate the nature of interactions in MTSs, such as valuable  
30  
31 learning functions within and between teams. Further, while we assessed interactions during a  
32  
33 key action phase of the MTS lifecycle that is especially relevant for external interactions and  
34  
35 team processes (DeChurch & Marks, 2006), it would also be useful to examine interactions  
36  
37 during transition phases. We were unable to do so because of incomplete sensor data over this  
38  
39 time; but, a fuller examination across the lifecycle of an MTS would enhance understanding of  
40  
41 coordination phases (Mathieu et al., 2018). This issue of timing also relates to our measurement  
42  
43 of conflict after the action phase and sensor measurement of interactions. It is possible that there  
44  
45 are recursive relations between conflict and interpersonal interactions, such that conflicts arising  
46  
47 from an initial imbalance in intrateam and inter-team interactions spurs a change in members'  
48  
49 interaction patterns. In this regard, in spite of assessing constructs at multiple time points, we are  
50  
51  
52

54  
55  
56  
57  
58  
59  
60

1  
2  
3 unable to establish causality given our methodology. Research is needed, perhaps leveraging  
4 computational modeling or experimental designs, to examine how cycles of informal  
5 coordination emerge in MTSs across time, and their causal effects on conflict and performance.  
6  
7

8  
9  
10 Our hypothesis regarding system-level performance presumed knowledge exchange as a  
11 mechanism stemming from congruence in intrateam and inter-team interactions. While we did  
12 not directly measure this system-level mechanism, Argote and Ingram (2000) noted that  
13 interactions among members are a potent mechanism for transferring knowledge. A more in-  
14 depth examination of knowledge sharing, acquisition, and assimilation processes within MTSs is  
15 needed, especially at the system level. Future research should examine system-level mediating  
16 mechanisms such as knowledge transfer and inter-team conflict, to attempt to mirror our findings  
17 at the team level. Future research could also examine the connections among these interactions  
18 and knowledge transfer to learning and performance within the MTS context.

29

### 30 **Conclusion**

31  
32 Our study highlights the role of informal coordination mechanisms for overcoming  
33 performance tensions in MTSs. For knowledge-based MTSs, balanced informal interpersonal  
34 interactions—when intrateam interactions correspond to inter-team interactions—provide an  
35 informal coordination mechanism. When interactions are unbalanced, they engender conflict that  
36 threatens team and ultimately MTS performance. Our findings invite renewed attention to the  
37 potential role of informal mechanisms for enabling coordination within the context of MTSs.

**A: Sample Layout of MTS Rube Goldberg Machine**

*Note.* Each component team built their local machine within a 3 foot by 2 foot area at their own separate workstation and then subsequently connected it to adjacent teams’ machines to create the overall system based on the pattern above (the particular method and location of connection between adjacent teams was determined based on mutual discussion and coordination among adjacent teams). The final energy output of transferring sugar to a cup of coffee was completed by the last team in the system.

## Appendix A: Procedure for Processing Bluetooth Signal Detection Data

### Overview of Measurement Procedure

The wearable multi-sensor devices (i.e., Kim et al., 2012) we utilized have been used in other studies of teams (e.g., Bernstein & Turban, 2018; Parker, Cardenas, Dorr, & Hackett, 2018). The devices comprise infrared sensors, microphones, an accelerometer, and Bluetooth technology and were accompanied by proprietary software used to process sensor output (Kim et al., 2012). Although recent papers have raised important questions about the quality of some of the measures derived from these sensors (e.g., Chaffin et al., 2017, Kayhan, Chen, French, Allen, Salomon, & Watkins, 2018), validation efforts have also suggested that the Bluetooth sensors in the devices can yield a valid measure of physical proximity if researchers use the raw signal information that the sensors record, rather than derivative metrics output by the software (Chaffin et al., 2017; Matusik et al., 2019; Müller et al., 2020).

We took several steps to reduce the likelihood of systematically biased measures of interpersonal interactions in MTSs. First, to guard against the potential for individual devices to systematically vary in their sensitivity to physical proximity (i.e., Chaffin et al., 2017), we randomly assigned devices to individual participants on a week-by-week basis. Second, we retrieved and used the raw Bluetooth detection data, which records any instance when two Bluetooth sensors detect one another and establish a connection. The strength of the signal serves as the key indicator of physical proximity and was the basis of our operationalization of interpersonal interactions (Chaffin et al., 2017; Matusik et al., 2019; Müller et al., 2020). Third, we adopted a threshold-based approach for determining whether a Bluetooth signal detection event constituted an interpersonal interaction. Consistent with Matusik et al. (2019), we considered a range of signal strength values (i.e., -91 to -69) as potential thresholds for determining whether a given detection event constituted an interaction. We report results using a threshold value of -80—the value at the midpoint of the signal strength range that we considered. Appendix B provides the results of sensitivity analyses used to assess the degree to which our findings were dependent on a particular threshold value. The results of these analyses build confidence in the robustness of our findings to a particular threshold.

### Sample Dataset Excerpt Used in Example Below

Using an example, we explain below the process that we used to calculate intrateam and inter-team interactions.

1	3	1	4	2	2	2	2	2	2	2	2	20
1	3	2	7	3	3	2	1	1	0	0	0	9

In addition to summing across the dyadic interactions, there is also now a variable (*min*) to indicate the number of simultaneously recording minutes for the pair's sensors. That is, *min* gives the number of minutes time that a's and b's sensors were simultaneously in operation. This information is gleaned from the output provided by each badge.

### Step 3a: Compute team-level intrateam interactions

The purpose of Step 3 is to aggregate the dyad-level data to the team-level. We first did so for intrateam interactions—interactions between individuals who belong to the same component team. For a given team, we thus summed the interactions that took place between individuals with the same team identifier. Further, we summed to the team level the total number of minutes for these same dyadic observations. Note that the sample interaction table does not contain Team 2's intrateam interaction data. Were the sample to be extended, Team 2 would similarly have values for intrateam interactions.

team_id	t_91	t_90	t_89	t_88	t_87	t_86	t_85	t_84	min
1	17	17	17	17	16	16	15	15	88
2	...								

Our measure of team-level intrateam interactions is a given threshold variable (i.e.,  $t_{##}$ ) divided by *min*.

### Step 3b: Compute team-level inter-team interactions

Next, we computed team-level inter-team interactions—interactions between individuals who belong to different component teams. For a given team, we thus summed the interactions that took place between individuals of the focal team with someone with a different team identifier. And, again, we summed to the team level the total number of minutes for these same dyadic observations. We have again excluded Team 2's data, which are only partially represented in the sample dataset. Were the sample to be extended, Team 2 would similarly have values for inter-team interactions.

team_id	t_91	t_90	t_89	t_88	t_87	t_86	t_85	t_84	min
1	8	8	7	6	6	4	4	4	59
2	...								

Our measure of team-level inter-team interactions is a given threshold variable (i.e.,  $t_{##}$ ) divided by *min*.

### Step 4: Aggregate to the system level

To compute system-level intrateam and inter-team interactions, we calculated the system-level mean (i.e., across teams) of the variables created in Steps 3a and 3b.

## Appendix B: Results of Analyses Examining Sensitivity of Results to Different RSSI Threshold Values

The following tables provide the results of analyses conducted to examine the sensitivity of our results to different RSSI Threshold values. Müller et al. (2020) demonstrated that while higher RSSI values typically indicate devices being closer together, there are a variety of factors that can impact it (cubicle walls, clothing over the sensor, etc.). Given these factors, RSSI values should be interpreted in terms of closer proximity or greater distance, rather than as precise measures of distance (Müller et al. 2020). We therefore examined a range of RSSI values to examine the sensitivity of the findings. Each table represents a single regression model, linked to our primary Results section. We considered a total of 23 threshold values, ranging from -91 to -69 (inclusive). Thus, each summary statistic below is based on a distribution of 23 parameter estimates extracted from separate models run at these threshold values. The table summarizes the distribution of t-values for each variable (i.e., parameter estimate divided by its standard error) in the model across multiple RSSI threshold values. Focal variables highlighted in our results section are in bold font.
